Introduction

A. Summary

The pET Express & Purify Kits and the pET Express & Purify Kits (In-Fusion® Ready) allow you to clone and express a his-tagged protein of interest in E. coli, using traditional restriction enzyme cloning or In-Fusion HD technology, respectively—and then to purify your protein using a choice of Immobilized Metal Ion Affinity Chromatography (IMAC) resins. The pET Express & Purify Kits are supplied with high-affinity HisTALON™ gravity columns and buffers for optimal purity (Cat. No. 631430) or with high-capacity His60 Ni gravity columns and buffers (Cat. No. 631431) for optimal yield. The pET Express & Purify Kits (in-Fusion Ready) are also available in HisTALON (Cat. No. 631429) and His60 Ni (Cat. No. 631428) formats (Figure 1).

Bacterial expression is typically the first approach to the production of proteins for in vitro studies, due to its simplicity and robustness. The pET Express & Purify Kits have been designed to expedite the use of bacterial expression by incorporating a number of technologies that increase the efficiency of each of these steps. This system, which is based on the inducible T7 expression system (pET) developed by F. William Studier and colleagues at Brookhaven National Laboratories (Moffatt & Studier, 1986, Rosenberg et al., 1987, Studier et al., 1990), contains IPTG-inducible, pET-based vectors providing high levels of protein expression.

Figure 1. The pET Express & Purify Kits and pET Express & Purify Kits (In-Fusion Ready) protocol. A gene of interest is cloned into a pET6xHN vector, a pET-based expression vector, to generate an N- or C-terminal-tagged construct. The pET Express & Purify Kits allow a choice of cloning sites, while the pET Express & Purify Kits (In-Fusion Ready) provide the option of easy, precise In-Fusion HD PCR cloning to yield a 6xHN-tagged construct. After transformation and growth in E. coli, the expressed N- or C-terminal-tagged protein is efficiently purified using either a HisTALON gravity column for the highest purity of the target protein or a His60 Ni Superflow gravity column for the highest binding capacity.
B. Choice of cloning options

The pET6xHN Expression Vector Set provided with the pET Express & Purify Kits contains two separate bacterial expression vectors encoding N- or C-terminal 6xHN fusion tags (pET6xHN-N and pET6xHN-C, respectively), which provide a variety of cloning options (see Figure 2). These vectors, which are circular, contain multiple cloning sites and can be used for traditional restriction enzyme cloning.

The pET6xHN Expression Vector Set (In-Fusion Ready) provided with the pET Express & Purify Kits (in-Fusion Ready) contains prelinearized versions of these vectors, utilizing our In-Fusion technology to provide seamless (no addition of base pairs), easy, low-background directional cloning of PCR products, without the need for restriction enzyme digestion, subcloning, or in vitro ligation.

See Sections V and VI for details regarding these two cloning methods.

![Figure 2. Cloning options using the pET Express & Purify Kits.](image)

C. Tightly regulated expression

The vectors supplied with these systems contain the hybrid T7 lac promoter, as well as a lacI gene, which encodes Lac repressor (Dubendorff & Studier, 1991). This combination reduces expression in the absence of inducer, while allowing for rapid inducibility upon addition of IPTG to the bacterial culture (see Figure 3). This reduces background expression levels, since Lac repressor binds to the lac operator present adjacent to the T7 promoter.

D. Easy purification

The provided vectors are designed to incorporate 6xHN tags at the amino- or carboxy-terminus of the protein of interest, allowing for convenient purification using IMAC resins. The 6xHN tag is short enough not to interfere with protein biological activity and function, and long enough not to be internalized.

The pET Express & Purify Kits and the pET Express & Purify Kits (in-Fusion Ready) are each available with your choice of prefilled gravity columns and buffers to perform extraction and purification of histagged proteins. Choose HisTALON Co resin to achieve the highest purity of your target protein—or choose His60 Ni Superflow resin when a high binding capacity is required.
Figure 3. The molecular basis of the pET system for recombinant protein expression in DE3 lysogens. Tight regulation is achieved by the presence of lac operator sites in two promoters: the lac UV5 promoter that controls expression of T7 RNA polymerase (integrated into the genome of the DE3 lysogen) and the hybrid T7 lac promoter that controls expression of the gene of interest. In the absence of inducer (IPTG), Lac repressor (expressed from both genomic and plasmid-derived lacI genes) binds tightly to the operator sites to repress transcription. When IPTG is added during induction, Lac repressor releases from the operators, allowing expression of T7 RNA polymerase, which then acts on the newly derepressed T7 lac promoter. The thick arrows refer to expression of gene products, while the thin arrows indicate molecular interactions.

II. List of Components
For storage conditions, refer to the Certificate of Analysis supplied with each component.

A. pET Express & Purify Kits

pET Express & Purify Kit—HisTALON (Cat. No. 631430)
- pET6xHN Expression Vector Set (see Section II.C.1)
- HisTALON Gravity Columns (5 columns) (also sold separately as Cat. No. 635655)
- HisTALON Buffer Set (see Section II.D) (also sold separately as Cat. No. 635651)

pET Express & Purify Kit—His60 (Cat. No. 631431)
- pET6xHN Expression Vector Set (see Section II.C.1)
- His60 Ni Gravity Columns (5 columns) (also sold separately as Cat. No. 635657)
- His60 Ni Buffer Set (Cat. No. 635665) (see Section II.D) (also sold separately as Cat. No. 635665)
B. **pET Express & Purify Kits (In-Fusion Ready)**

**pET Express & Purify Kit—HisTALON (In-Fusion-Ready) [Cat. No. 631429]**
- pET6xHN Expression Vector Set (In-Fusion Ready) [see Section II.C.2]
- HisTALON Gravity Columns (5 columns)
  (also sold separately as Cat. No. 635655)
- HisTALON Buffer Set (see Section II.D)
  (also sold separately as Cat. No. 635651)

**pET Express & Purify Kit—His60 (In-Fusion-Ready) [Cat. No. 631428]**
- pET6xHN Expression Vector Set (In-Fusion Ready) [see Section II.C.2]
- His60 Ni Gravity Columns (5 columns)
  (also sold separately as Cat. No. 635657)
- His60 Ni Buffer Set (Cat. No. 635665) [see Section II.D]
  (also sold separately as Cat. No. 635665)

C. **Vector Set Components**

1. **pET6xHN Expression Vector Set**
   - 20 µl pET6xHN-N Vector (500 ng/µl)
   - 20 µl pET6xHN-C Vector (500 ng/µl)
   - 10 µl pET6xHN-GFPuv Vector (500 ng/µl)

2. **pET6xHN Expression Vector Set (In-Fusion Ready)**
   - 15 µl pET6xHN-N Vector (In-Fusion Ready) [100 ng/µl]
   - 15 µl pET6xHN-C Vector (In-Fusion Ready) [100 ng/µl]
   - 10 µl pET6xHN-GFPuv Vector [500 ng/µl]
   - 15 µl 1.1 kb LacZ-RK Control Insert [25 ng/µl]
   - 20 µl 5X In-Fusion HD Enzyme Premix

D. **Buffer Set Components**

**HisTALON Buffer Set**
- 2 bottles HisTALON Equilibration Buffer (250 ml per bottle)
- 1 bottle HisTALON Elution Buffer (200 ml each)
- 1 bottle HisTALON xTractor Buffer (100 ml each)

**His60 Ni Buffer Set**
- 2 bottles His60 Ni Equilibration Buffer (250 ml per bottle)
- 1 bottle His60 Ni Elution Buffer (200 ml each)
- 1 bottle His60 Ni xTractor Buffer (100 ml each)
III. Additional Materials Required

The following materials are required but not supplied:

- **Advantage® HD Polymerase Mix** (Cat. Nos. 639241) for amplifying your gene of interest
- **NucleoSpin Extract II Kit** (Cat. No. 740609.50) for purification of vector and insert (if using pET Express & Purify Kits), or purification of insert (if using pET Express & Purify Kits (in-Fusion Ready))
- **DNA Ligation Kit, Ver 1.0** (TAKARA Bio USA, Cat. No. TAK 6021) or **DNA Ligation Kit, Ver 2.1** (TAKARA Bio USA, Cat. No. TAK 6022)
- **Sprint™ Advantage Single Shots** (Cat. No. 639553) for colony PCR screening
- **NucleoSpin QuickPure** (Cat. No. 740615.50) or **NucleoSpin Plasmid** (Cat. No. 740588.50) for purification of positive clones following colony screening
- **xTractor Buffer** (Cat. No. 635656) for solubility analysis and extraction of expressed proteins
- **ProteoGuard EDTA-Free Protease Inhibitor Cocktail** [Cat. Nos. 635672 (for 100 µl) & 635673 (for 10 x 100 µl)]
- **5X SDS loading buffer**
  - 15% β-mercaptoethanol
  - 15% SDS
  - 50% glycerol
  - 1.5% bromophenol blue
- **BL21 (DE3) competent bacteria** (EMD Biosciences, Inc.)
- **ampicillin** (100 mg/ml stock)
- **LB (Luria-Bertani) medium** (pH 7.0) for 1 L
  - 1.0% Bacto-tryptone (10 g)
  - 0.5% yeast extract (5 g)
  - 1.0% NaCl (10 g)

Dissolve ingredients in 950 ml of deionized H₂O. Adjust the pH to 7.0 with 5 M NaOH and bring the volume up to 1 L. Autoclave on liquid cycle for 20 min at 15 lb/in². Store at room temperature or 4°C.

- **LB/antibiotic plates**
  Prepare LB medium as above, but add 15 g/L of agar before autoclaving. Autoclave on liquid cycle for 20 min at 15 lb/in². Let cool to ~55°C, add antibiotic (e.g., 100 µg/ml of ampicillin), and pour into 10 cm plates. After the plates harden, then invert and store at 4°C. For LB/X-Gal/IPTG plates, spread 40 µl each of X-Gal and IPTG stock solutions on an LB plate.

- **X-Gal stock solution** (5-bromo-4-chloro-3-indolyl-b-D-galactoside; 40 mg/ml in dimethylformamide)
  Dissolve 400 mg X-Gal in 10 ml of dimethylformamide. Protect from light by storing in a brown bottle at –20°C.

- **IPTG stock solution** (isopropyl-b-D-thiogalactoside; 100 mM)
  Dissolve 238 mg IPTG in 10 ml of deionized H₂O. Filter-sterilize and store in 1 ml aliquots at –20°C.
IV. General Considerations

A. Traditional Cloning Method
Choose the pET Express & Purify Kits (Cat. Nos. 631430 & 631431), which contain circular vectors, for traditional restriction enzyme-based cloning. Using traditional cloning methods (i.e., ligation-based cloning of compatible DNA fragments) provides a choice of several cloning sites (Figure 2), provided that these sites are not found internally in the DNA fragment to be cloned. Traditional cloning may be more convenient if the fragment to be cloned contains restriction sites in frame with the gene of interest. For detailed vector maps, please see the Certificate of Analysis supplied with each kit, which is also available at www.clontech.com

B. In-Fusion Cloning Method
Choose the pET Express & Purify Kits (in-Fusion Ready) (Cat. Nos. 631429 & 631428), which contain prelinearized vectors designed to be used with Clontech’s In-Fusion HD technology.

In-Fusion HD cloning provides several advantages over restriction enzyme-based cloning:

- **Directional cloning** of PCR products into linearized vectors without the need for restriction digests, ligation, or blunt end polishing. This is more convenient than restriction enzyme-based cloning, and allows the use of restriction sites that are present within the fragment to be cloned.

- **No restriction digestion.** Since the vectors are provided in prelinearized form (using Sal I and Hind III), there is no need to digest the vector prior to cloning. In-Fusion cloning is based on homology between the ends of the linearized vector and the PCR product—this homology is introduced into the PCR product via the use of PCR primers with 5’ extensions.

- **Clone the same PCR product into both vectors** in parallel. The pET6xHN-N (In-Fusion Ready) and pET6xHN-C (In-Fusion Ready) vectors have been designed so that the sequences 5’ to the Sal I site and 3’ to the Hind III site are the same in both vectors. This allows cloning of the same PCR product into both vectors in parallel, which is convenient for comparing expression and purification of your protein when a 6xHN tag is attached to either the amino or the carboxy terminus, respectively. Furthermore, these PCR products are compatible with all of our prelinearized fluorescent protein vectors, allowing you to easily switch to a different expression system, depending on your needs.

C. Vector Maps
The vector maps and multiple cloning site information for each of the pET Express system vectors are provided in the Certificate of Analysis supplied with each kit, which is also available at www.clontech.com
V. Traditional Cloning Protocol

**PLEASE READ THE ENTIRE PROTOCOL BEFORE STARTING**

Traditional cloning consists of many steps. These include primer design, PCR amplification, and cleanup of the PCR insert; or cleavage from an existing vector and insert cleanup. The vector must also be cleaved and cleaned up. This is followed by T4 DNA ligation, transformation, and screening of inserts. We recommend the DNA Ligation Kit, Ver. 1.0 (TAKARA Bio USA, Cat. No. TAK 6021) or the DNA Ligation Kit, Ver. 2.1 (TAKARA Bio USA, Cat. No. TAK 6022).

A. PROTOCOL: Cloning Site Selection and PCR Primer Design

Use the following criteria to select restriction sites for cloning and to design PCR primers for generating the DNA insert:

- Choose appropriate restriction sites based on the absence of these sites within the DNA insert to be cloned.
- These sites should be incorporated into PCR primers which are then used to PCR-amplify the sequence to be cloned.
- These primers should be carefully designed to ensure that the reading frame of your gene aligns with the ATG start codon which forms part of the Nco I site at the 5’ end of the MCS.
- Make certain to design your 5’ primer **WITHOUT** the ATG start codon of the wild type protein.
- Sufficient flanking sequence should be incorporated to ensure efficient digestion of the PCR product using the appropriate restriction enzymes. We recommend six nucleotides 5’ to the restriction enzyme recognition sequence.

**NOTES:**

- The MCS is designed with overlapping Pac I sites at the 3’ end. This ensures that all three reading frames contain a stop codon. If the Pac I site is used for cloning, only one of the sites in the vector will be cut. Thus, be sure that your intended stop codon is found in the first Pac I site. That way, the stop codon will be in frame regardless of which Pac I site in the vector is digested.
- The Xba I site is 3’ to the Pac I sites, and is therefore not followed by stop codons. If you use the Xba I site for cloning, be sure that your insert contains its own stop codon.
B. PROTOCOL: Generating a Gene-Specific Expression Vector

Generate your recombinant expression construct using standard molecular biology techniques, as described below. For more detailed information, see Molecular Cloning: A Laboratory Manual (Sambrook & Russell, 2001) or Current Protocols in Molecular Biology (Ausubel et al., 2001).

1. **Digest** the pET6xHN vector with the restriction enzyme(s) appropriate for your expression application, treat with phosphatase (if desired), and purify.

**NOTES:**
- The ends of the fragment to be cloned must be compatible with one or more restriction sites present in the cloning vector. This can be accomplished by PCR-amplifying the fragment using primers that contain suitable restriction sites.
- If cloning with the 6xHN affinity tag included in the vector, ensure that the correct reading frame is maintained (see the MCS of the appropriate vector for the alignment of restriction sites with the open reading frame that begins with the initiation codon (ATG) within the Nco I site).

2. **Purify** the insert using any standard method. We recommend using the NucleoSpin Extract II Kit (Cat. No. 636972). This kit can be used for PCR clean-up or gel purification.

3. **Ligate** the digested vector and the gene fragment.

4. **Transform** chemically competent or electrocompetent bacterial cells (we recommend Clontech’s Stellar™ Electrocompetent Cells (Cat. No. 636765) with a sample of the ligation mixture and plate on LB agar plates containing 100 μg/ml ampicillin.

5. **Identify** the desired recombinant plasmid by colony PCR, restriction analysis of miniprepped DNA, and/or sequencing of miniprepped DNA. For colony PCR, we recommend using Sprint Advantage Single Shots (Cat. No. 639553).

6. **Transform** into BL21 DE3 or other strain containing DE3 for expression analysis (see Section VIII).
VI. In-Fusion Cloning Protocol

A. PROTOCOL: PCR Cloning of Your PCR Insert into the pET6xHN Vectors (In-Fusion Ready)

The following method describes a simple and highly efficient method to clone your gene in parallel into the pET6xHN Vectors (In-Fusion Ready). The magic of In-Fusion means:

- One-step directional cloning (Figure 4)
- Seamless cloning—no addition of unwanted base pairs
- No restriction digestion, phosphatase treatment, or ligation
- Clone the same PCR fragment in parallel into both expression vectors

![Single-tube protocol](image)

Figure 4. Simple, one-step cloning with In-Fusion HD PCR Cloning Kits.

1. **Design** your primers with a 15 bp homology. See the In-Fusion HD Cloning Kit User Manual (PT5162-1) at [www.clontech.com](http://www.clontech.com) for In-Fusion PCR primer design guidelines.

2. Amplify your PCR insert by using a high-fidelity enzyme such as Advantage HD Polymerase Mix (Cat. No. 639241).

3. **Purify** the PCR product using NucleoSpin Extract II (Cat. No 636972). With this kit you can gel-purify or spin-column purify—the choice is yours.

   OR

   **Treat with Cloning Enhancer** (Cat. No. 639613) if you see a single specific band in your PCR reaction. Cloning Enhancer removes background plasmid DNA and PCR residue, eliminating the need for PCR insert purification.

4. **Clone**. Combine your PCR insert and linearized vectors with the In-Fusion HD Enzyme and incubate. (The same PCR insert can be cloned into both C-term and N-term vectors).

5. **Transform and screen** colonies for the correct insert.

See the In-Fusion HD Cloning Kit User Manual (PT5162-1) at [www.clontech.com](http://www.clontech.com) for additional details regarding the PCR cloning procedure.
VII. Protein Expression Protocol

A. General Considerations

Once the desired expression plasmid has been obtained, you may induce expression of your protein using IPTG, according to the following recommendations:

- First, the plasmid must be transformed into *E. coli* strain BL21 DE3 (EMD Biosciences, Inc.), which contains the T7 polymerase gene under the control of the lac repressor.
- It is recommended to use freshly transformed bacteria or frozen glycerol stocks for expression experiments, since continued culture or long periods of storage on plates can result in loss of expression.

The following protocols are provided for the analysis of protein expression, including protein solubility. This small-scale approach is also useful for optimizing expression conditions. The expression protocol can be scaled up for production, and IMAC purification can be performed using either HisTALON Co resin for the highest purity or His60 Ni Superflow resin for the highest binding capacity—with the prefilled gravity columns and buffers provided in your kit.

B. PROTOCOL: Expression Protocol (Small-Scale)

1. Pick colonies to innoculate small (2–4 ml) LB/amp cultures and shake overnight at 37°C (ampicillin concentration is 100 μg/ml).
   
   In the morning, innoculate a 4–50 ml culture by diluting the overnight culture 1/20 to 1/50 with LB amp.

2. Shake until an OD of 0.6–0.8 is reached, set aside a small volume of culture (~1 ml) on ice to serve as an uninduced control, and then add IPTG to a concentration of 1 mM. Continue shaking at 37°C for 4–5 hr.

3. Centrifuge samples at 1,000–3,000 x g for 15 min at 4°C, remove supernatant, and freeze pellets at –80°C for further analysis.
C. **PROTOCOL: Analysis of Expression**

You have the option to analyze total protein expression (when analyzing a number of samples), or proceed directly to analyzing solubility (see Section D). Protein solubility is essential when planning the purification protocol, since some eukaryotic proteins are insoluble when expressed in bacteria and form inclusion bodies. The trade-off of insolubility is that these proteins tend to be expressed at high levels, and isolation of inclusion bodies is an effective initial purification step:

**Total expression can be analyzed by SDS-PAGE as follows:**

1. Resuspend pellets in 1/10th of the original culture volume using PBS, add an equal volume of 2X SDS loading buffer (see Section III), and mix well. (It is OK to mix samples on a vortex mixer, but avoid forming bubbles if you intend to sonicate the samples.)

2. The samples can then be sonicated for 30 sec, or drawn through a 27 gauge needle 4 or 5 times. This will reduce the viscosity of the sample due to genomic DNA and thus facilitate gel loading. An alternative is to centrifuge the sample for 5 min just prior to loading the gel and use the supernatant, taking care to avoid the pellet when pipetting.

3. Heat the sample to 95°C for 3–5 minutes, centrifuge briefly, and proceed to load the gel. Samples may be stored at –20°C.

D. **PROTOCOL: Analysis of Solubility**

There are numerous successful protocols for improving solubility and refolding proteins from inclusion bodies. In the latter case, the protein must be solubilized using denaturants prior to purification. IMAC purification using TALON resin works under both native and denaturing conditions. This protocol will allow you to separate soluble and insoluble (inclusion body) fractions and then analyze these by SDS-PAGE.

1. Resuspend the cell pellets in xTractor Buffer:
   a. Add 20 μl xTractor Buffer per mg of cell pellet or 40 μl per ml of the original culture volume.
   b. Incubate at room temperature for 20–30 min (the incubation with xTractor Buffer can be carried out on ice for 45–60 min).

   **NOTE:** Add DNAse to xTractor Buffer if the resulting sample is very viscous.

2. Alternatively, resuspend the cell pellets in 1X Equilibration Buffer as follows:
   a. Resuspend the cell pellets in a volume of the provided 1X Equilibration Buffer equivalent to 1/10th the original culture volume (chilled to 4°C).
   b. Add lysozyme to a concentration of 0.75 mg/ml. To reduce the chance of introducing proteases, use the highest purity lysozyme available.
   c. Sonicate your sample 3 x 10 sec, with a 30 sec pause on ice between each burst.

3. Centrifuge the cell extract at 10,000–12,000 x g for 20 min at 4°C to pellet insoluble material.

4. Carefully transfer the supernatant to a clean tube without disturbing the pellet. This is the clarified sample.
5. Reserve a portion for SDS/PAGE analysis. The remainder may be kept for a trial purification using TALON resin. Keep the remainder on ice until it is used for purification (carry out the purification within 2–4 hr after the extraction).

6. Resuspend the pellet in a volume of 1X Equilibration Buffer equivalent to the volume used in Step 1. Add an equal volume of 2X SDS sample buffer.

7. The resuspended pellet can then be sonicated for 30 sec, or drawn through a 27 gauge needle 4 or 5 times. This will reduce the viscosity of the sample due to genomic DNA, and thus facilitate gel loading. An alternative is to centrifuge the sample for 5 min just prior to loading the gel, and take care to avoid the pellet when pipetting.

8. Heat the samples corresponding to both the soluble and insoluble fractions at 95°C for 3–5 min and centrifuge briefly.

9. Analyze samples by SDS-PAGE. Add to this an equivalent volume of 2X SDS Sample Buffer. Typically, a sample equivalent to 25–50 μl of culture volume will produce clean bands on a gel. This corresponds to 5–10 μl of sample when processed according to the above instructions.

10. If you wish to identify the target protein band, use our Universal HIS Western Blot Kit (Cat. No. 635633) after transferring the bands to a PVDF membrane.

Appendix A: pET Expression Vector Information

The **pET6xHN Expression Vector Set** (Section II; Figure 5), and the **pET6xHN Expression Vector Set (In-Fusion Ready)** (Section II; Figure 6) each contain two separate bacterial expression vectors that allow you to express your protein of interest with an N- or C-terminal 6xHN tag, respectively—as well as a control vector that expresses an N-terminal, 6xHN-tagged GFPuv fusion protein. For complete descriptions of the vectors provided with each system, refer to the enclosed Certificate of Analysis, which is also available at [www.clontech.com](http://www.clontech.com).
